Process for producing spherical catalyst particles, catalyst particles  
and their use in chemical synthesis

The present invention relates to a method for producing spherical catalyst particles containing a zeolite as active element, to catalyst particles containing a zeolite as active element and to the use of these particles in epoxidation reactions.

It is known, for instance from the European patent application EP-A2-0 200  
5 260, to use microspheres having an average diameter close to 20  $\mu\text{m}$  and constituted by oligomeric silica and by titanium-silicalite crystals as catalyst particles for the epoxidation of olefins. It is further known that such catalysts tend to deactivate and that they consequently need to be regenerated regularly. When these catalyst particles of relative small average diameter are used as such in  
10 epoxidation reactors, they are difficult to isolate from the reaction medium in order to be transferred to the regeneration treatment. In order to avoid this problem, larger catalyst particles can be used. However, these particles present a lower activity and inferior mechanical properties. Moreover, the known relatively small particles are not suitable for use in a fluid bed reactor because at a normal  
15 velocity of the fluid, they tend to be carried over.

It is an object of the invention to provide a method for the production of spherical catalyst particles which permits the shaping of particles which are suitable to be isolated easily from the reaction medium and which present a high catalytic activity and good mechanical properties.

20 Consequently, the invention concerns a process for producing spherical catalyst particles containing a zeolite as active element, according to which a sol containing zeolite crystals and at least one gel-forming compound is sprayed from below directly into a reaction zone containing a reaction gas such that the sol breaks up into individual sol beads immediately before or upon entry into the  
25 reaction zone, the sol beads flow through the reaction zone on a curved trajectory, in so doing are pre-consolidated and the sol beads are collected on a collecting means.

One of the essential characteristics of the invention is that the particle size range of the sol beads can be modulated and controlled by the kind of spraying  
30 device used and this particle size range can be maintained without deformation during the process due to the special process conditions. Consequently, the size

range of the catalyst particles can easily be controlled. This allows the production of catalyst particles of the desired granulometry, which makes it possible to easily isolate them from the (epoxidation) reaction medium, to have a high catalytic activity and good mechanical properties.

5 Another advantage of the invention is that the place and time of the formation of the sol beads is advantageously matched to the beginning of gelling (pre-consolidation) of the sol beads. This means that at the time at which the sol beads are produced, they are still liquid sol drops having a virtually ideal spherical shape and largely identical sphere diameters. The sol beads are then fixed, i.e. pre-consolidated, in their virtually ideal uniform spherical shape as they pass through  
10 the reaction zone, so that they are largely protected from deformative effects. Finally the sol beads pre-consolidated in their spherical shape are stably fixed by additional known measures of the generally known sol-gel process. To this end, the spraying-in device is arranged at a certain distance (as described below) below  
15 the entry opening into the reaction zone. This distance corresponds approximately to the distance, starting from the spraying device, in which the sol breaks up into sol beads. In addition, the sol is sprayed out of the spraying device from below, i.e. counter to the force of gravity. This means that the sol is sprayed at a given angle  $\alpha$  which is formed by a horizontal axis at right-angles to the force of gravity  
20 and the tangent of the sprayed sol at the exit point from the spraying system.

The process according to the invention is suitable for the production of catalyst particles containing zeolite as active element by gelling gellable sols containing zeolite crystals and one or more gel-forming compounds.

"Zeolite" is to be understood to mean synthetic crystalline materials  
25 presenting a zeolite crystalline structure. The zeolite crystals can have a crystalline structure of the ZSM-5 type. The zeolite crystals can also have a structure of the ZSM-11 or MCM-41 type. They advantageously contain oxides of silicon and titanium. Usually the zeolite crystals contain at most 2 % by weight of titanium. Zeolite crystals of the titanium silicalite type are preferably used. They are in  
30 particular represented by the formula  $x\text{TiO}_2(1-x)\text{SiO}_2$  in which  $x$  is from 0,0001 to 0,5 and preferably from 0,001 to 0,05. The zeolite crystals present advantageously an infrared absorption band at approximately  $950\text{-}960\text{ cm}^{-1}$ . The best results are obtained with zeolite crystals of the TS-1 type which presents a microporous crystalline zeolite structure of the ZSM-5 type wherein several  
35 silicon atoms are replaced by titanium atoms. The properties of these TS-1 crystals are known (B. Notari; Structure-Activity and Selectivity Relationship in

Heterogeneous Catalysis; R.K. Grasselli and A.W. Sleight Editors; Elsevier; 1991; p. 243-256). Their synthesis is also known (A. Van der Poel and J. Van Hooff, Applied Catalysis A, 1992, volume 92, pages 93-111). The zeolite crystals used generally present an average diameter of at most 10  $\mu\text{m}$ . The average  
5 diameter is generally of at least 0,1  $\mu\text{m}$  but can even be smaller. Average diameters ranging from 1 to 5  $\mu\text{m}$  are preferred. Such crystals present the advantage that the mechanical strength of the catalyst particles is improved.

The zeolite crystals and the gel-forming compound are generally used in a quantity such that the catalyst particles contain from 5 to 95 wt % of zeolite  
10 preferably from 20 to 50 wt %.

The gel-forming compounds can be based on inorganic oxides such as magnesium oxide, aluminium oxide, silicon dioxide, aluminosilicate, zinc oxide, titanium dioxide, chromium oxide, manganese oxide, cerium oxide, tin oxide, iron  
oxide, nickel oxide, lead oxide, molybdenum oxide, vanadium oxide, thorium  
15 oxide, zirconium oxide and/or hafnium oxide. Preferred gel-forming compounds are based on silicon dioxide. The sols can in addition to the gel-forming compounds contain additional additives which can improve the use-related and/or catalytic properties of the catalyst particles.

According to the process of the invention a gellable sol containing zeolite  
20 crystals and at least one gel-forming compound is sprayed from bottom to top into the reaction zone at an angle which depends on the dimensions of the equipment used. The angle is preferably such that the flow of sol beads does not touch the walls of the equipment. In practice the angle is often chosen from 80 to 88°. Depending on the particle size range, syringes with cannulae of different  
25 diameters or known spray nozzles, centrifugal discs, spray wheels, ultrasonic nozzles or bells, spray guns, turbo bells, magnetic valves, mechanically operated nozzles or spraying systems, such as are used in electrostatic spraying or in jet printers (e.g. piezo-excited nozzles), may be used as spraying devices. The particle size range in this case is varied by means of the spraying device used. For  
30 a desired particle size in the range from 0,01 mm to 0,3 mm, therefore, expediently turbo bells, micromagnetic valves or spray nozzles, e.g. known spiral nozzles (e.g. spiral nozzles manufactured by SPRAYBEST) or preferably ultrasonic nozzles are used. For a desired particle size in the range from 0,3 to 5 mm, in particular 0,3 mm to 3,5 mm, expediently spray wheels or preferably  
35 cannulae of corresponding diameter are used. If there is a very short distance from the spraying device to the entry opening of the reaction zone containing the

reaction gas, it may be expedient, e.g. when using spray nozzles or cannulae of small diameter, to blow on the spraying device with a purge gas (e.g. compressed air or water vapour), in order thus to avoid clogging of the spraying device by prematurely gelling sol.

5       According to a first variant, the sol is in the form of an instable sol obtained by combining two components, e.g. by mixing together an alkaline component with an acidic component. One of these two components can contain the zeolite crystals. For example, a sol containing zeolite crystals and silicon dioxide, which can be used in the process of the invention, can be obtained by mixing together as  
10       alkaline component an aqueous solution of an alkali metal silicate, e.g. a sodium silicate solution, with the aqueous solution of an inorganic acid, e.g. an aqueous sulphuric acid or hydrochloric acid solution, or an organic acid, e.g. an aqueous formic acid or acetic acid solution in known manner. The zeolite crystals are preferably incorporated in the acidic component. Both the alkaline and acidic  
15       component may in this case have added additional constituents, for example aluminium or magnesium compounds. An instable sol containing zeolite crystals and silicon dioxide can also be obtained by reacting silicic acid alkyl ester with an alkaline component, e.g. with NaOH, NH<sub>3</sub> or an acidic component, e.g. with hydrochloric acid, or silicon tetrachloride with an acid component, e.g. with  
20       aqueous formic acid. In this case, the zeolite crystals are preferably not incorporated in the alkaline component.

      According to a second variant, the sol is in the form of a metastable sol which does not gel until it makes contact with the reaction gas. Metastable silica sols, e.g. BAYER S200<sup>®</sup>, can be used.

25       Sols which contain additional components in homogeneous or heterogeneous form can also be used. As heterogeneous components, they may for example contain fines of any known type, quantity and particle size. In order to improve the use-related properties, for example fillers may be added as fines. Mineral fillers are advantageously added to improve the mechanical strength and the water  
30       resistance of the catalyst particles. Organic fillers as well as inorganic fillers can modify the porosity of the catalyst particles. The mineral fillers can be chosen from silicic acids, aluminosilicates, aluminium oxides, titanium dioxide, kaolin, montmorillonite, bentonite. The organic fillers can be chosen from starch, wood flour or activated carbon. These fillers may be added to the acidic and/or alkaline  
35       component in crystalline or amorphous form, or alternatively in highly-dispersed form. Fines which change the catalytic properties of the particles may also be used

in conventional manner. Examples of homogeneous components which can be added are magnesium, zirconium, copper, lead or titanium acetyl acetonates.

The mixing of the alkaline component to the acidic component to form a gellable instable sol can be performed in known manner in any mixing device  
5 suitable for the purpose, e.g. a mixing nozzle. Then the sol thus obtained is pumped directly into a spraying device, with which it can be sprayed into the reaction gas from below.

The process of the invention can be carried out using the device described in the international patent application WO 94/20203, in particular the devices of  
10 figures 1 or 2.

In the process of the invention, the sol beads, at the moment of their formation, are subjected to the gelling action of the reaction gas practically immediately. The breaking down of the sol into individual sol beads depends on the viscosity of the sol, the spraying device and the pressure with which the sol  
15 leaves the spraying device, in addition to the angle. It is advantageous that the point of breakup of the sol into individual sol beads is located immediately before or in the entry opening of the reaction zone.

After entering the reaction zone, the sol beads formed pass through the reaction gas located in the reaction zone on a curved trajectory (parabola-like form), and in so doing are fixed in their spherical shape, i.e. are pre-consolidated.  
20 The reaction gas can therefore contribute to the pre-consolidation of the sol beads for a particularly long time, so that this already minimises the risk of deformation of the sol beads when they hit the collecting device. By additionally heating the reaction zone, e.g. to approximately 200 °C, the pre-consolidation can be  
25 optionally further supported. In order to reduce still further the risk of deformation, if desired a collection device which is adjustable in height can be brought in close to the point of reversal of the parabolic trajectory of the sol beads, at which the sol beads have their lowest kinetic energy.

A film stretched flat, such as a PVDF film or polyethylene or PVC film, or a  
30 smooth collecting plate or a collecting container filled with liquid can be used as the collecting device in the process of the invention. When using a smooth collecting plate, this can be cooled as such, or a plate covered uniformly with solid carbon dioxide can be used. Particularly preferred process variants use a collecting container filled with a liquid, e.g. with water or preferably with a  
35 reaction liquid, as collecting device. "Reaction liquids" are to be understood to mean all conventional acidic or alkaline liquids used for ageing particles.

Customary reaction liquids for this purpose are aqueous ammonia solution, e.g. a 5 to 10 % aqueous ammonia solution, or acidic reaction liquids such as hydrochloric acid, sulphuric acid or nitric acid in concentrations of 1 to 5 % by weight. Acidic liquids are preferred. When using a reaction liquid, expediently reaction gases equivalent thereto should be used in the reaction zone. If e.g. an aqueous ammonia solution is provided as reaction liquid, ammonia gas or vapours of organic amines should be used as reaction gas. When using acidic reaction liquids such as hydrochloric acid, sulphuric acid or nitric acid, the acidic reaction gases equivalent thereto, i.e. hydrogen chloride, sulphur dioxide or nitrogen oxides should be used.

When using self-gelling sols, inert gases such as air or oxygen can also be used as reaction gases. In this case, the pre-consolidation of the sol particles can be supported by heating the reaction zone. Temperatures below room temperature can also be used in the reaction zone.

From the collecting device, the pre-consolidated sol particles can be washed, dried and optionally calcined. Drying is usually carried out at temperatures in the range from 100 to 200 °C for a period of 1 to 24 hours. In one variant, the pre-consolidated sol particles, when using a film stretched flat or a smooth collecting plate as collecting device, can also be converted directly into a drying unit, e.g. into a known spray dryer.

The spherical particles obtained according to the process of the invention, may also be subjected to a treatment with a lower alkyl alcohol, in particular a C<sub>1</sub> to C<sub>4</sub> alcohol or to treatment with acetone, before they are sent for drying once they have been collected in the collecting device. Due to this treatment firstly advantageously agglutination of the resulting particles (especially those having an average diameter of less than 1 mm) can be avoided during drying, and secondly the pore volume of the resulting particles can be expanded.

One of the advantages of the process according to the invention is that it permits the shaping of particles which are as uniformly spherically shaped as possible, with a narrow grain spectrum and narrow pore diameter distribution. So, the occurrence of relatively large quantities of undersize or oversize can be largely avoided. Furthermore, the particles produced demonstrate high abrasion resistance.

By means of the process of the invention, it is possible to obtain spherical catalyst particles containing zeolite as active element, which have :

(a) a diameter in the range of 0,01 to 5 mm, preferably 0,02 to 3,5 mm.

Diameters in the range of 100 to 200  $\mu\text{m}$  are particularly suitable for catalyst particles used in slurry processes. Diameters in the range of 500  $\mu\text{m}$  to 1 mm are convenient for catalyst particles used in fluid bed reactors. Diameters in the range of 750  $\mu\text{m}$  to 1 mm are convenient in fixed bed reactors.

- 5 (b) a specific surface area in the range of 1 to 900  $\text{m}^2/\text{g}$ , preferably 100 to 800  $\text{m}^2/\text{g}$  (measured according to recording and evaluation of nitrogen sorption curves),
- (c) a bulk density in the range of 0,1 to 1,0  $\text{g}/\text{ml}$ ,
- (d) a pore volume in the range of 0,25 to 2,5  $\text{ml}/\text{g}$  (measured according to  
10 mercury porosimetry or recording and evaluation of nitrogen sorption curves),
- (e) a distribution of the pore diameters having a maximum (monomodal pore distribution) in the range of 15 to 2000  $\text{\AA}$ , preferably 15 to 400  $\text{\AA}$  (measured according to mercury porosimetry or recording and evaluation of nitrogen  
15 sorption curves).

Furthermore, the invention covers the use of the spherical particles described above as catalysts for chemical synthesis. The catalyst particles can in particular be used in epoxidation reactions of olefinic compounds using a peroxide. Good results are obtained in the epoxidation of allyl chloride with the aid of hydrogen  
20 peroxide into 1,2-epoxy-3-chloropropane. They can also be used in the epoxidation of propylene with hydrogen peroxide into 1,2-epoxypropane.

The invention also concerns a process for the epoxidation of olefinic compounds with the aid of a peroxide in the presence of the above described catalyst particles containing a zeolite as the active element. The olefinic  
25 compound is preferably allyl chloride or propylene. The peroxide is preferably hydrogen peroxide.

The following example is intended to explain the invention but without restricting it.

Example 1 (according to the invention)

30 An aqueous suspension of TS-1 crystals of an average diameter of 2,5  $\mu\text{m}$  containing 19,2 wt % of the crystals has been prepared. 2440 g of this suspension has been mixed with 2108 g of a 19,4 wt % sulphuric acid solution. This mixture (1) has been injected in a device similar to that shown in figure 1 of the international patent application WO 94/20203 together with an alkaline  
35 waterglass solution (2) containing 5,0 wt %  $\text{Na}_2\text{O}$  and 16,8 wt %  $\text{SiO}_2$ . The co-injection was carried out in such a manner that a sol was formed of (1) and (2)

which presented a pH of 6,9. The device contained air as reaction gas. The collecting device was filled with water. The collected particles have been washed with water and calcined at 550 °C during 6 hours. The particles thus obtained contained 36 wt % of TS-1 (the rest being silica) and presented a specific surface area of 431 m<sup>2</sup>/g, a bulk density of 0,52 g/ml, a pore volume of 0,75 cm<sup>3</sup>/g (BET N<sub>2</sub>). 97,5 wt % of the particles had a diameter of 1 to 1,4 mm, less than 0,2 wt % of the particles had a diameter greater than 1,4 mm, less than 2,5 wt % of the particles had a diameter smaller than 1 mm and less than 0,4 wt % of the particles had a diameter smaller than 0,85 mm. The particles presented a pore diameter comprised within the range from 15 to 160 Å and an average pore diameter of 55 Å.

### CLAIMS

- 1 - Process for producing spherical catalyst particles containing a zeolite as active element, according to which a sol containing zeolite crystals and at least one gel-forming compound is sprayed from below directly into a reaction zone containing a reaction gas such that the sol breaks up into individual sol beads immediately before or upon entry into the reaction zone, the sol beads flow through the reaction zone on a curved trajectory, in so doing are pre-consolidated and the sol beads are collected on a collecting means.
- 2 - Process according to claim 1, in which the zeolite crystals have a crystalline structure of the ZSM-5, ZSM-11 or MCM-41 type.
- 3 - Process according to claim 2, in which the zeolite crystals contain oxides of silicon and titanium.
- 4 - Process according to claim 3, in which the zeolite crystals present an infrared absorption band at approximately  $950-960\text{ cm}^{-1}$ .
- 5 - Process according to claim 4, in which the zeolite crystals are represented by the formula  $x\text{TiO}_2(1-x)\text{SiO}_2$  in which x is from 0,0001 to 0,5 and preferably from 0,001 to 0,05.
- 6 - Process according to any of the preceding claims, in which the sol contains fines.
- 7 - Process according to any of the preceding claims, in which a container filled with a reaction solution is used, in particular an aqueous ammonia solution in combination with ammonia used as reaction gas, or an aqueous acid chosen from the group of hydrochloric acid, sulphuric acid or nitric acid in combination with hydrogen chloride or sulphur dioxide or nitrogen oxide used as reaction gas.
- 8 - Catalyst particles containing zeolite as active element presenting
- (a) a diameter in the range of 0,01 to 5 mm, preferably 0,02 to 3,5 mm,
  - (b) a specific surface area in the range of 1 to  $900\text{ m}^2/\text{g}$ , preferably 100 to  $800\text{ m}^2/\text{g}$  (measured according to recording and evaluation of nitrogen sorption curves),
  - (c) a bulk density in the range of 0,1 to 1,0 g/ml,

- (d) a pore volume in the range of 0,25 to 2,5 ml/g (measured according to mercury porosimetry or recording and evaluation of nitrogen sorption curves),
  - (e) a distribution of the pore diameters having a maximum (monomodal pore distribution) in the range of 15 to 2000 Å, preferably 15 to 400 Å (measured according to mercury porosimetry or recording and evaluation of nitrogen sorption curves).
- 5

9 - Use of the catalyst particles from claim 10 in chemical synthesis.

- 10 - Use according to claim 9 for epoxidation reactions of olefinic compounds, preferably allyl chloride or propylene, with the aid of a peroxide, preferably hydrogen peroxide, into an epoxide, preferably 1,2-epoxy-3-chloropropane or 1,2-epoxypropane.
- 10
